A Joint Valuation of Premium Payment and Surrender Options in Participating Life Insurance Contracts

Hato Schmeiser, Joël Wagner

Institute of Insurance Economics
University of St. Gallen, Switzerland

Singapore, July 2010
Abstract

• Life insurance contracts typically embed, in addition to an interest rate guarantee and annual surplus participation,
  ▶ a paid-up option, the right to stop payments during the contract term,
  ▶ a resumption option, the right to resume payments, and,
  ▶ a surrender option, the right to terminate the contract early.

• Terminal guarantees on benefits payable upon death, survival and surrender are adapted after option exercise.

• Model framework and algorithm to jointly value the options is developed.

• Standard principles of risk-neutral evaluation are applied; the policyholder is assumed to use an economically rational exercise strategy.

• Option value sensitivity on different contract parameters, benefit adaptation mechanisms, and exercise behavior is analyzed numerically.
Adequate risk management needed for correct valuation of options and compliance with regulation rules

- Financial crisis and variable annuity products with embedded options have highlighted the importance of the valuation and the risk management of options.
- Current and planned regulation rules prescribe risk-adequate capital deposits for embedded options.
  → E.g. Solvency II, SST, NAIC RBC, and IFRS.
- Hypotheses on the policyholder’s exercise behavior are required to evaluate option values, in particular with regard to stress-testing of products.
  → How much more value can policyholders get by exercising differently than what has been observed?
Competitive advantage for product design and pricing when knowing the "fair" price

- Separate inspection of embedded options with regard to pricing and risk management.
  → *Pricing flexibility through reconfiguration of the conversion mechanism of the guaranteed benefits after exercise of the option.*

- Product design and offering of products along the needs and willingness to pay of customers.
  → *Possibility of offering zero-valued options, not to be paid for by the client.*

- Adequate and "fair" pricing of embedded options since policy inception.
  → *Competitive advantage.*
1. Introduction

Literature review of selected scientific contributions I

- Fair pricing of contracts with a guaranteed interest rate and different annual surplus participations.
  → *E.g.* Bacinello (2001); Hansen and Miltersen (2002); Tanskanen and Lukkarinen (2003); Ballotta et al. (2006); Branger et al. (2010).

- Surrender option, on top of guaranteed interest rate and surplus participation.
  → *E.g.* Grosen and Jorgensen (2000); Jensen et al. (2001).

- Surrender option in Italian life insurance contracts with single and periodic premiums, including mortality risk.
  → *E.g.* Bacinello (2003a,b, 2005); Bacinello et al. (2009).

- Surrender option in French life insurance contracts.
  → *E.g.* Albizzati and Geman (1994).

- Surrender and paid-up options with underlying stochastic interest rates and deterministic surplus participation.
  → *E.g.* Herr and Kreer (1999).
1. Introduction

Literature review of selected scientific contributions II

- Numerical analysis of risk-neutral valuation of embedded options and broad overview on numerical techniques. → E.g. Bauer et al. (2006); Bauer et al. (2008).

- Analysis of paid-up options in German government-subsidized pension products based on different assumptions about the policyholder’s exercise behavior. → E.g. Kling et al. (2006).

- Option valuation through an optimal feasible exercise strategy in the case of one Bermudan-style embedded option. → E.g. Barraquand and Martineau (1995); Andersen (1999); Douady (2002); Kling et al. (2006).
What is the contribution of this work?

- Model framework and methodology closest to the following:
  - Gatzert and Schmeiser (2008): paid-up and resumption options with focus on the maximal risk.

- Key features:
  - Several options are valued jointly.
    → *Most works consider options separately.*
  - Pricing through assumptions on policyholder’s behavior is given.
    → *Not only assessment of maximal risk potential.*
  - Exercise through economically rational optimal strategy.
    → *Feasible strategy.*
  - Analysis of option values for various benefit conversion mechanisms in a policy assets perspective.
    → *Perspective allows for asset transparency in comparison with reserve-linked modeling.*
1. Introduction

Structure of this talk

- **Introduction of the model framework**
  - Basic contract $B$ including interest guarantee and surplus participation.
  - Contract $P$ with a paid-up option $O^P$.
  - Contract $R$ with a combined paid-up and resumption option $O^R$.
  - Contract $S$ featuring a surrender option $O^S$.
  - Contract $Q$ with a combined paid-up and surrender option $O^Q$.

- **Option valuation techniques and exercise behavior hypotheses**
  - Maximum over all times of exercise of the option payoff.
  - *Option value* reached using an optimal admissible exercise strategy.
  - Upper bound of the option payoff for any exercise strategy (risk).

- **Numerical results and discussion**
  - Option values for different contracts and parameters.
  - Sensitivity analysis of the model.
Basic contract $\mathcal{B}$

- **Life insurance contract with periodic premium payments featuring**
  - an interest rate guarantee $g$, and,
  - an annual surplus participation, i.e. fraction $\alpha$ of the surplus.
- **Premium payments** $B_{t-1}$, $t = 1, \ldots, T$, are paid annually at the beginning of the $t$th policy year given the insured remains alive.  
  $\rightarrow$ *Annual premium payments $B_t \equiv B$ are supposed constant.*
- **Mortality statistics:** financial risk and mortality risk are uncorrelated; mortality risk is eliminated by writing a sufficiently large number of contracts (actuarial practice).  
  $\rightarrow$ *Mortality risk does not contain systematic risk.*
- **Survival and death probabilities:**
  - $t p_x$: $x$-year-old policyholder survives for the next $t$ years.
  - $t q_x = 1 - t p_x$: $x$-year-old dies within the next $t$ years.
  - $q_{x+t}$ (resp. $p_{x+t}$): $(x + t)$-year-old policyholder will die within the next year, between $t$ and $t + 1$ (resp. survive one more year, the $t$th year).
- **Guarantees are on benefits payable upon death and survival.**  
  $\rightarrow$ *Contract $\mathcal{B}$ non-surrenderable and without paid-up option.*
Death benefit

- In case of death during the $t$th year of the contract, the assigned policyholder’s beneficiary receives $\Upsilon^B_t \equiv \Upsilon^B$ at the end of the year.
- Actuarial equivalence principle: the expected value of the payments to the insured equals the expected premium payments from the insured:

$$B \sum_{t=0}^{T-1} t p_x (1 + g)^{-t} = \Upsilon^B \left( \sum_{t=0}^{T-1} t p_x q_{x+t} (1 + g)^{-(t+1)} + T p_x (1 + g)^{-T} \right).$$

- The death benefit is given by

$$\Upsilon^B = \frac{B \sum_{t=0}^{T-1} t p_x (1 + g)^{-t}}{\sum_{t=0}^{T-1} t p_x q_{x+t} (1 + g)^{-(t+1)} + T p_x (1 + g)^{-T}}.$$
Survival benefit I

- In case of survival until maturity $T$, the insurer pays out the accumulated policy assets $A_T^B$.
  \[ \rightarrow Including\ guaranteed\ interest\ and\ surplus\ participation.\]
- Annual premium payments $B$ are split into
  - Premium $B_{t-1}^R$ for term life insurance, used to buy insurance to cover the difference between the guaranteed death benefit $\gamma^B$ and the available policy assets $A_{t-1}^B$. For the $t$th year, fair pricing implies that
    \[ B_{t-1}^R = q_{x+t-1} \max(\gamma^B - A_{t-1}^B, 0). \]
  - Savings premium $B_{t-1}^A = B - B_{t-1}^R$.
    \[ \rightarrow Credited\ to\ the\ policy\ assets\ at\ the\ beginning\ of\ the\ tth\ year. \]
- $A_{t-1}^B$ and $B_{t-1}^A$ annually earn the greater of the the guaranteed interest rate $g$ or a fraction $\alpha$ of the annual surplus $(S_t/S_{t-1} - 1)$. 
Survival benefit II

- Life insurer’s investment portfolio $S_t$ follows a geometric Brownian motion given a complete, perfect, and frictionless market. For $t = 1, \ldots, T$, $S_t$ is defined by

$$dS_t = \mu S_t dt + \sigma S_t dW_t^P,$$

with deterministic asset drift $\mu$, volatility $\sigma$, and a $P$-Brownian motion $W^P$.

- Under the risk-neutral unique equivalent martingale measure $Q$, the drift of the process is the risk-free interest rate $r$, and

$$S_t = S_{t-1} \exp \left[ r - \sigma^2/2 + \sigma(W_t^Q - W_{t-1}^Q) \right],$$

with $Q$-Brownian motion $W^Q$ and initial condition $S_0$ (see, e.g., Björk (2004)).
Survival benefit III

• Finally, the accumulated policy assets $A^B_t$, $t = 1, \ldots, T$, can be calculated as follows,

$$A^B_t = \left( A^B_{t-1} + t_{-1}p_x B^A_{t-1} \right) (1 + \max [g, \alpha(S_t/S_{t-1} - 1)])$$

$$= \left( A^B_{t-1} + t_{-1}p_x \left[ B - q_{x+t-1} \max(\gamma^B - A^B_{t-1}, 0) \right] \right) \cdot (1 + \max [g, \alpha(S_t/S_{t-1} - 1)]) ,$$

with $A^B_0 = 0$. 

J. Wagner, A Joint Option Valuation in Participating Life Insurance Contracts, WRIEC, Singapore, July 2010
Contract payoff $I$

- Payoff $P_T^B$ at maturity $T$ is determined by the payments to the insured less the premium payments, compounded with the risk-free rate $r$:

$$P_T^B = \sum_{t=0}^{T-1} \gamma_t^B p_x q_{x+t} e^{r(T-t-1)} + p_x A_T^B - \sum_{t=0}^{T-1} B_t p_x e^{r(T-t)}.$$

- Let $\Pi_0^B$ denote the net present value of the contract payoff $P_T^B$ at time $t = 0$. With $E_t^Q$ denoting the conditional expected value with respect to the probability measure $Q$ under the information available in $t$, one gets

$$\Pi_0^B = E_0^Q \left( e^{-rT} P_T^B \right).$$
2. Model framework – Basic contract \( B \)

Contract payoff II

- **Contract is *fair* if the present value of the benefits under the risk neutral martingale measure is equal to the present value of premiums paid by the policyholder (see, e.g., Doherty and Garven (1986)):**

  \[
  \Pi_0^B = 0.
  \]

- **All other parameters given, the annual surplus participation parameter \( \alpha \) can be calibrated to obtain fair contracts.**

  → *I.e. the two options in the basic contract, interest guarantee and surplus participation, are covered by the annual premium payments.*
Contract $\mathcal{P}$ with paid-up option and death benefit

- Contract $\mathcal{P}$ based on basic contract $\mathcal{B}$.
- Paid-up option $\mathcal{O}^\mathcal{P}$: policyholder has the right to exercise $\mathcal{O}^\mathcal{P}$ (once) annually until maturity. → $\mathcal{O}^\mathcal{P}$ is a Bermudan-style option.
- After exercising $\mathcal{O}^\mathcal{P}$ at time $t = \tau$, $\tau = 1, \ldots, T - 1$, denoted by $\mathcal{O}^\mathcal{P}(\tau)$, and given the policyholder is still alive, the terminal benefits are adjusted according to a mechanism described below.
- **Adjusted death benefit** calculated by taking the accumulated policy assets $A^\mathcal{B}_\tau$ as single premium for a new contract,

$$\gamma^\mathcal{P}(\tau) = \frac{A^\mathcal{B}_\tau (1 + \gamma^\mathcal{P}_\tau)}{\sum_{t=\tau}^{T-1} t - \tau p_{x+\tau} q_{x+t} (1 + g)^{-(t-\tau+1)} + T - \tau p_{x+\tau} (1 + g)^{-(T-\tau)}}$$

with $\gamma^\mathcal{P}_\tau$ a model parameter, with default value 0. → Parameter represents flexibility to adapt benefits.
Survival benefit and contract payoff

- **Adjusted survival benefit** given by $A^P_T(\tau)$, where $A^P_t(\tau)$, $t = \tau, \ldots, T$, denote the accumulated policy assets over time after exercising $O^P$ at time $\tau$:

$$A^P_t(\tau) = \left( A^P_{t-1}(\tau) - t-1 \rho_x q_{x+t-1} \max(\gamma^P(\tau) - A^P_{t-1}(\tau), 0) \right) \cdot (1 + \max [g, \alpha(S_t/S_{t-1} - 1)]) ,$$

with $A^P_{\tau}(\tau) = A^B_{\tau}(1 + \gamma^P_{\tau})$.

- **Contract payoff** at maturity $T$, in the case the paid-up option is exercised in $\tau$, is given by

$$P^P_T(\tau) = \sum_{t=0}^{\tau-1} \gamma^B_t \rho_x q_{x+t} e^{r(T-t-1)} + \sum_{t=\tau}^{T-1} \gamma^P(\tau) t \rho_x q_{x+t} e^{r(T-t-1)} + T \rho_x A^P_T(\tau) - \sum_{t=0}^{\tau-1} B_t \rho_x e^{r(T-t)} .$$
Paid-up option value

- The value at time $t = 0$ of the paid-up option $O^P(\tau)$ exercised at time $\tau$ can be residually determined by the difference of the contract values of $P$ and $B$:

$$\Pi_0(O^P(\tau)) = E^Q_0 \left[ e^{-rT} \left( P^P_T - P^B_T \right) \right] = E^Q_0 \left[ e^{-r\tau} \tau p_x C_\tau(O^P(\tau)) \right],$$

where

$$C_\tau(O^P(\tau)) = \sum_{t=\tau}^{T-1} \left( \gamma^P(t) - \gamma^B(t) \right) t_{-\tau} p_{x+t} q_{x+t} e^{-r(t-\tau+1)} + \left( A^P_T - A^B_T \right) T_{-\tau} p_{x+T} e^{-r(T-\tau)} + \sum_{t=\tau}^{T-1} B_{t-\tau} p_{x+t} e^{-r(t-\tau)}.$$

- Since the basic contract is fair, we have $\Pi_0^P(\tau) = \Pi_0(O^P(\tau)).$
2. Model framework – Contract $\mathcal{R}$ with paid-up and resumption options

Contract $\mathcal{R}$ with paid-up and resumption options I

- Contract $\mathcal{R}$ based on contract $\mathcal{P}$ with paid-up option.
- Combined paid-up and resumption option $\mathcal{O}^{\mathcal{R}}$: right to stop premium payments at time $\tau = 1, \ldots, T - 1$, and to resume payments at time $\nu = \tau + 1, \ldots, T - 1$.
  \[ \mathcal{O}^{\mathcal{R}}(\tau, \nu) \text{ denotes the combined exercise at times } \tau \text{ and } \nu. \]
- Death benefit

\[
\gamma^{\mathcal{R}}(\tau, \nu) = \frac{A^{\mathcal{P}}(\tau)(1 + \gamma^{\mathcal{R}}) + B \sum_{t=\nu}^{T-1} t_{-\nu} p_{x+\nu} (1 + g)^{-(t-\nu)}}{\sum_{t=\nu}^{T-1} t_{-\nu} p_{x+\nu} q_{x+t} (1 + g)^{-(t-\nu+1)} + T_{-\nu} p_{x+\nu} (1 + g)^{-(T-\nu)}} \]

with $\gamma^{\mathcal{R}}$ a model parameter, with default value 0.
Contract $\mathcal{R}$ with paid-up and resumption options II

- **Survival benefit** given by $A_{t}^{\mathcal{R}(\tau,\nu)}$, with $A_{t}^{\mathcal{R}(\tau,\nu)}$, $t = \nu + 1, \ldots, T$:

  $$A_{t}^{\mathcal{R}(\tau,\nu)} = \left(A_{t-1}^{\mathcal{R}(\tau,\nu)} + t-1 p_x \left[B - q_{x+t-1} \max(\gamma^{\mathcal{R}(\tau,\nu)} - A_{t-1}^{\mathcal{R}(\tau,\nu)}, 0)\right]\right)$$

  $$\cdot \left(1 + \max[g, \alpha(S_t/S_{t-1}-1)]\right),$$

  with $A_{\nu}^{\mathcal{R}(\tau,\nu)} = A_{\nu}^{\mathcal{P}(\tau)}(1 + \gamma_{\nu}^{\mathcal{R}})$.

- **Contract payoff** at maturity $T$:

  $$P_{T}^{\mathcal{R}(\tau,\nu)} = \sum_{t=0}^{\tau-1} \gamma^{B} t p_x q_{x+t} e^{r(T-t-1)} + \sum_{t=\tau}^{\nu-1} \gamma^{\mathcal{P}(\tau)} t p_x q_{x+t} e^{r(T-t-1)}$$

  $$+ \sum_{t=\nu}^{T-1} \gamma^{\mathcal{R}(\tau,\nu)} t p_x q_{x+t} e^{r(T-t-1)} + \tau p_x A_{T}^{\mathcal{R}(\tau,\nu)}$$

  $$- \sum_{t=0}^{\tau-1} B_t p_x e^{r(T-t)} - \sum_{t=\nu}^{T-1} B_t p_x e^{r(T-t)}.$$
2. Model framework – Contract $\mathcal{R}$ with paid-up and resumption options

**Contract $\mathcal{R}$ with paid-up and resumption options III**

- **Option value** at $t = 0$:

  $$\Pi_0(\mathcal{O}^\mathcal{R}(\tau,\nu)) = E_0^Q \left[ e^{-rT} \left( P_T^\mathcal{R}(\tau,\nu) - P_T^\mathcal{B} \right) \right] = E_0^Q \left[ e^{-r\tau} p_x C_\tau(\mathcal{O}^\mathcal{R}(\tau,\nu)) \right],$$

  where

  $$C_\tau(\mathcal{O}^\mathcal{R}(\tau,\nu)) = \sum_{t=\tau}^{\nu-1} \left( \gamma^\mathcal{P}(\tau) - \gamma^\mathcal{B} \right) t-\tau p_{x+\tau} q_{x+t} e^{-r(t-\tau+1)}$$

  $$+ \sum_{t=\tau}^{T-1} \left( \gamma^\mathcal{R}(\tau,\nu) - \gamma^\mathcal{B} \right) t-\tau p_{x+\tau} q_{x+t} e^{-r(t-\tau+1)}$$

  $$+ \left( A_T^\mathcal{R}(\tau,\nu) - A_T^\mathcal{B} \right) T-\tau p_{x+\tau} e^{-r(T-\tau)}$$

  $$+ \sum_{t=\tau}^{\nu-1} B_{t-\tau} p_{x+\tau} e^{-r(t-\tau)}.$$
2. Model framework – Contract $S$ with surrender option

Contract $S$ with surrender option I

- **Contract $S$ based on basic contract $B$.**
- **Surrender option $O^S$ exercisable at time $\theta = 1, \ldots, T - 1$.**
  → *Contract is terminated: death benefit annihilated, surrender benefit paid out at $t = \theta$.*
- **Surrender benefit**

$$A^{S(\theta)}_\theta = A^B_\theta (1 + \gamma^S_\theta),$$

where $\gamma^S_\theta$ is a parameter with default value 0.
- **Contract payoff** at the time of surrender $t = \theta$:

$$P^{S(\theta)}_\theta = \sum_{t=0}^{\theta-1} \gamma^B t p_x q_{x+t} e^{r(\theta-t-1)} + \theta p_x A^{S(\theta)}_\theta - \sum_{t=0}^{\theta-1} B t p_x e^{r(\theta-t)}.$$
Option value at $t = 0$:

$$
\Pi_0(\mathcal{O}^S(\theta)) = E_0^Q \left[ e^{-r\theta} \left( P_{\theta}^S(\theta) - e^{-r(T-\theta)} P_{\theta}^B \right) \right] = E_0^Q \left[ e^{-r\theta} p_\theta C_{\theta}(\mathcal{O}^S(\theta)) \right],
$$

where

$$
C_{\theta}(\mathcal{O}^S(\theta)) = - \sum_{t=\theta}^{T-1} \gamma^B_{t-\theta} p_{x+\theta} q_{x+t} e^{-r(t-\tau+1)} + \left( A_S^S(\theta) - A_T^B T-\theta p_{x+\theta} e^{-r(T-\theta)} \right) + \sum_{t=\theta}^{T-1} B_{t-\theta} p_{x+\theta} e^{-r(t-\theta)}. \nonumber
$$
2. Model framework – Contract $Q$ with paid-up and surrender options

Contract $Q$ with paid-up and surrender options

- **Contract $Q$** based on contract $P$ with paid-up option.

- **Combined paid-up and surrender option $O^Q$**: right to stop premium payments at time $\tau = 1, \ldots, T - 1$, and to surrender the contract at time $\theta = \tau + 1, \ldots, T - 1$.

- **Surrender benefit** at time $\theta$ when contract has been paid-up at $t = \tau$:
  \[
  A^Q_{\theta, (\tau, \theta)} = A^P_{\theta, \tau} (1 + \gamma^Q_{\theta}),
  \]
  where $\gamma^Q_{\theta}$ is a parameter with default value 0.

- **Contract payoff** at the time of surrender $t = \theta$:
  \[
  P^Q_{\theta, (\tau, \theta)} = \sum_{t=0}^{\tau-1} \gamma^B_t p_x q_{x+t} e^{r(\theta-t-1)} + \sum_{t=\tau}^{\theta-1} \gamma^P(\tau) p_x q_{x+t} e^{r(\theta-t-1)} \]
  \[
  + \theta p_x A^Q_{\theta, (\tau, \theta)} - \sum_{t=0}^{\tau-1} B_t p_x e^{r(\theta-t)}.
  \]
2. Model framework – Contract $Q$ with paid-up and surrender options

**Contract $Q$ with paid-up and surrender options II**

- **Option value at $t = 0$:**

\[
\Pi_0(Q^{\tau,\theta}) = E^Q_0 \left[ e^{-r\theta} \left( P^Q\theta(\tau,\theta) - e^{-r(T-\theta)} P^B_T \right) \right] = E^Q_0 \left[ e^{-r\theta} \theta p_x C_\theta(Q^{\tau,\theta}) \right],
\]

where

\[
C_\theta(Q^{\tau,\theta}) = \sum_{t=\tau}^{\theta-1} \left( \gamma^P(\tau) - \gamma^B \right) t_\theta p_{x+\theta} q_{x+t} e^{-r(t-\tau+1)}
\]

\[
- \sum_{t=\theta}^{T-1} \gamma^B t_\theta p_{x+\theta} q_{x+t} e^{-r(t-\tau+1)}
\]

\[
+ \left( A^Q(\tau,\theta) - A^B_T T_\theta p_{x+\theta} e^{-r(T-\theta)} \right)
\]

\[
+ \sum_{t=\tau}^{T-1} B^\tau t_\theta p_{x+\theta} e^{-r(t-\theta)}.
\]
Option valuation I

- Valuation of options is connected to the policyholder’s exercise behavior.
- Different ways to approach the valuation of the embedded options, e.g.,
  - the maximum over all possible times of exercise of the expected value of the option payoff,
  - the *option value* that can be reached using an optimal admissible exercise strategy,
  - the upper bound of the option payoff for any exercise strategy.
- 1st and 3rd approaches suppose the policyholder to know the future for choosing the optimal time of exercise.
  → *This is not, in practice, a feasible strategy.*
- 3rd approach assesses the maximal risk potential on a possible path, see, e.g., Kling et al. (2006), Gatzert and Schmeiser (2008).
  → *Can be helpful for stress-testing of products.*
3. Option valuation – Maximum of expected option payoff

Maximum of expected option payoff

- Since the contract payoff is defined explicitly, the maximum over all exercise time(s) can be evaluated
- **Contract with one option**, \( X \in \{ P, S \} \):

\[
\Pi_0(O^X(\tau^*)) = \max_{\tau=1,\ldots,T-1} \left[ \Pi_0(O^X(\tau)) \right],
\]

where \( \tau^* \) denotes the exercise time maximizing \( \Pi_0(O^X(\tau)) \).

- **Contract with two options**, \( Y \in \{ R, Q \} \):

\[
\Pi_0(O^Y(\tau^*,\nu^*)) = \max_{\tau=1,\ldots,T-1,\nu=\tau+1,\ldots,T-1} \left[ \Pi_0(O^Y(\tau,\nu)) \right],
\]

where \( \tau^* \) and \( \nu^* \) denote the exercise times maximizing \( \Pi_0(O^Y(\tau,\nu)) \).
Optimal admissible exercise strategy

- Option valuation through considering a policyholder who follows an exercise strategy that maximizes the option value given the information available at the exercise date(s).
- Approach leads to an optimal stopping problem that can be solved using, for example, Monte Carlo simulation methods, as is done, e.g., in Andersen (1999), Douady (2002) or Kling et al. (2006).
- Whenever the underlying model for the economy has only one source of risk, an optimal admissible strategy for exercising Bermudan-style options can be found by looking only at the exercise value of the option, see Douady (2002).  
  → *This is apparently equivalent to considering only the current value of the accumulated policy assets in the present framework.*
- Extension of Kling et al. (2006) in a setting of a contract with two options.
Case of a contract with one option I

- Contract $\mathcal{X} \in \{\mathcal{P}, \mathcal{S}\}$ with one option $O^\mathcal{X}$ which can be exercised at times $\tau = 1, \ldots, T - 1$.
- Accumulated assets $A_t$ at times $t = 1, \ldots, T$, before exercise of the option.
- Payoff stream $C_\tau(O^\mathcal{X}(\tau))$ of the option at time $\tau$.
- Exercise strategy $K = K_1 \times \ldots \times K_{T-1} \subseteq \mathbb{R}^{T-1}$.
- Following this strategy, the option is exercised at time $\tau$ if and only if the option has not been exercised before and $A_\tau \in K_\tau$, i.e.,

$$1_{K_\tau}(A_\tau) = 1, \text{ and } 1_{K_t}(A_t) = 0, \forall t = 1, \ldots, \tau - 1.$$
Case of a contract with one option II

- Value of the option under the assumption that the investor applies some given strategy \( K \) is denoted by

\[
\Pi^K_0(OX) = E^Q_0 \left[ e^{-r \tau} p_x C_\tau(OX(\tau)) \right],
\]

where \( \tau = \inf \{ t \in \{1, \ldots, T - 1\} \text{ such that } A_t \in K_t \} \),

or \( \tau = T \), if \( A_t \notin K_t \), \( \forall t \in \{1, \ldots, T - 1\} \).

→ This last case where \( \tau = T \) corresponds to a strategy where the option is never exercised, and the value of the option is zero.

- Douady (2002) and Andersen (1999) describe the so-called value threshold method to approximate an optimal strategy, i.e., a strategy maximizing \( \Pi^K_0(OX) \) by Monte Carlo methods.

→ Existence of an optimal strategy \( K = (0; k_1] \times \ldots \times (0; k_{T-1}] \) for some \( k_t \in \mathbb{R}, t = 1, \ldots, T - 1 \) is shown.
Case of a contract with one option III

- Method uses a backward induction algorithm to determine the optimal values $k_1, \ldots, k_{T-1}$.

- Calculation of a Monte Carlo approximation follows two main parts:
  - the definition of the optimal exercise strategy $K$ (Algorithm 1), and,
  - the calculation of the approximation of the option value (Algorithm 2).

→ See Appendix.

- The value $\Pi^K_0(O^X)$, where $K$ is the optimal strategy, gives an approximation of the option value $\Pi_0(O^X)$. 
Case of a contract with two options 1

- Contract $\mathcal{Y} \in \{\mathcal{R}, \mathcal{Q}\}$ with a combined option $O^\mathcal{Y}$ exercisable at times $\tau = 1, \ldots, T - 1$ and $\nu = \tau + 1, \ldots, T - 1$.
- Accumulated assets $A_t$ at times $t = 1, \ldots, T$, before exercise of the first option, and $A_{(\tau)}^s$ the assets at times $s = \tau, \ldots, T$, where $\tau$ is the exercise date of the first option.
- Payoff stream $C_\tau(O^{\mathcal{Y}(\tau,\nu)})$ of the combined option at time $\tau$.
- Exercise strategy $K = K_1 \times \ldots \times K_{T-1} \subseteq \mathbb{R}^{T-1}$: the first option is exercised at time $\tau$ if and only if the option has not been exercised before and $A_\tau \in K_\tau$, i.e.,
  
  $1_{K_\tau}(A_\tau) = 1, \text{ and } 1_{K_t}(A_t) = 0, \forall t = 1, \ldots, \tau - 1.$

- For each exercise time $\tau = 1, \ldots, T - 1$, consider a corresponding exercise strategy $L^{(\tau)} = L_{\tau+1}^{(\tau)} \times \ldots \times L_{T-1}^{(\tau)} \subseteq \mathbb{R}^{T-\tau-1}$ with
  
  $1_{L_\nu^{(\tau)}}(A_{\nu}^{(\tau)}) = 1, \text{ and } 1_{L_s^{(\tau)}}(A_{s}^{(\tau)}) = 0, \forall s = \tau + 1, \ldots, \nu - 1.$
Case of a contract with two options II

- The value of the option under the assumption that the investor applies some given strategy $K$, followed by some strategy $L^{(\tau)}$ (for $\tau$ determined by $K$), is denoted by

$$\Pi_{0}^{K,L}(O^{\mathcal{Y}}) = E_{0}^{Q} \left[ e^{-r\tau} p_{x} C_{\tau}(O^{\mathcal{Y}(\tau,\nu)}) \right],$$

where $\tau = \inf \{ t \in \{1, \ldots, T - 1\} \text{ such that } A_{t} \in K_{t} \}$, or $\tau = T$, if $A_{t} \notin K_{t}$, $\forall t \in \{1, \ldots, T - 1\}$, and

where $\nu = \inf \{ s \in \{\tau + 1, \ldots, T - 1\} \text{ such that } A_{s}^{(\tau)} \in L_{s}^{(\tau)} \}$, or $\nu = T$, if $A_{s}^{(\tau)} \notin L_{s}^{(\tau)}$, $\forall s \in \{\tau + 1, \ldots, T - 1\}$.
Case of a contract with two options III

- *Nested* backward induction algorithm to determine the optimal values $k_t (t = 1, \ldots, T - 1)$, and $\ell^{(t)}_s (t = 1, \ldots, T - 1, s = t + 1, \ldots, T)$.
- The calculation of a Monte Carlo approximation is again done in two parts,
  - the definition of the optimal exercise strategies $K$ and $L^{(\tau)}$,
    - $\tau = 1, \ldots, T - 1$, and,
  - the calculation of the approximation of the option value.
- The value $\Pi_{0}^{K,L}(O^{\mathcal{Y}})$ through the application of optimal exercise strategies $K$ and $L^{(\tau)}$, gives the option value $\Pi_{0}(O^{\mathcal{Y}})$. 
Upper bound of the option payoff for any exercise behavior

- Behavioral-independent risk potential from embedded options.
  → *Policyholder knows the future and exercises the option at its maximum value.*

- Upper bound for the option price pointing out the potential hazards of offering such options, see Gatzert and Schmeiser (2008); Kling et al. (2006).
  → *This worst case from the product provider’s point of view does not correspond to a realistic strategy to expect from the clients.*

- **Contract with one option**, $\mathcal{X} \in \{\mathcal{P}, \mathcal{S}\}$:

$$
\Pi_{0}^{\max}(O^{\mathcal{X}}) = E_{0}^{Q} \left[ \max_{\tau=1, \ldots, T-1} \left( e^{-r\tau} p_{x} \max \left( 0, C_{\tau}(O^{\mathcal{X}(\tau)}) \right) \right) \right].
$$

- **Contract with two options**, $\mathcal{Y} \in \{\mathcal{R}, \mathcal{Q}\}$:

$$
\Pi_{0}^{\max}(O^{\mathcal{Y}}) = E_{0}^{Q} \left[ \max_{\tau=1, \ldots, T-1} \max_{\nu=\tau+1, \ldots, T-1} \left( e^{-r\tau} p_{x} \max \left( 0, C_{\tau}(O^{\mathcal{Y}(\tau,\nu)}) \right) \right) \right].
$$
Numerical results and discussion

Numerical simulation

- Monte Carlo simulation with antithetic variables and \( N = 1\,000\,000 \) different paths. → *Variance reduction by generating negatively correlated variables such that large and small outputs are counterbalanced* (see, e.g., Hull (2009, p. 433)).

- Average population mortality data derived from the Bell and Miller (2002) cohort life tables for the United States.

- Reference example with the following parametrization:
  - \( x = 30 \) and \( x = 50 \) year-old policyholders in 2010 at contract inception,
  - contract with time to maturity \( T = 10 \),
  - yearly premium payments \( B = 1200 \) (currency units),
  - risk-free interest rate \( r = 4\% \),
  - guaranteed interest rate \( g = 3\% \), and,
  - insurer’s investment portfolio with volatility \( \sigma = 0.20 \).

- First step: calibrate the fraction \( \alpha \) of the annual investment returns to get fair contract conditions.
  → *Standard bisection method is used to determine \( \alpha \) for given \( g \).*
Policy assets $A_t^B$, death benefit $Y^B$, and risk premium $B_t^R$

(a) Evolution of accumulated assets $A_t^B$ and death benefit $Y^B$ in contract $B$.

(b) Evolution of risk premium $B_t^R$ in contract $B$.

Figure: Death benefit, risk premium and accumulated assets for ages $x = 30, 50$ in basic contract $B$.

$\rightarrow$ With $x = 30$ and $x = 50$, $\alpha = 24.1\%$ and $\alpha = 29.3\%$ respectively.

$\rightarrow$ The standard error on the values reported for $A_t^B$ resp. $B_t^R$ are below $0.005\%$ resp. $0.05\%$, for all $t = 0, \ldots, T$. 
4. Numerical results and discussion – Basic contract B

Sensitivity of fair participation coefficient \( \alpha \)

(a) \( \alpha \) for different values \( T \)
   (with \( r = 4\% \), \( g = 3\% \), \( \sigma = 0.20 \)).

(b) \( \alpha \) for different values of \( r \)
    (with \( T = 10 \), \( g = 3\% \), \( \sigma = 0.20 \)).

(c) \( \alpha \) for different values of \( g \)
    (with \( T = 10 \), \( r = 4\% \), \( \sigma = 0.20 \)).

(d) \( \alpha \) for different values of \( \sigma \)
    (with \( T = 10 \), \( r = 4\% \), \( g = 3\% \)).
Policy assets $A^P_t(\tau)$, death benefit $Y^P(\tau)$, and $\Pi_0(O^P(\tau))$

(a) Assets $A^B_t$, $A^P_t(\tau)$ (solid lines), and death benefit $Y^B_t$, $Y^P(\tau)$ (dashed lines) in contract $P$ for different $\tau = 1, \ldots, 9$.

(b) Sensitivity analysis of $\Pi_0(O^P(\tau))$ for different $\gamma^P = \gamma^P = -1.5\%$, $\ldots$, $0.5\%$.

Figure: Analysis of contract $P$ with paid-up option.

→ Parameters: $T = 10$, $B = 1200$, $r = 4\%$, $\sigma = 0.20$, $g = 3\%$, $x = 30$. 
→ $\gamma^P = -1\%$ quasi annihilates the payoff for all exercise times.
4. Numerical results and discussion – Contract $\mathcal{P}$ with paid-up option

Table: Impact of fair and non-fair parameter \( \alpha \) on the option valuation. For reference, values for \( \Pi^B_0 \) are reported. Values reported in parentheses are the standard errors.

→ Firstly, let \( g = 1\% \) and \( g = 3\% \) and report valuation results for \( \alpha \) being such that the contract \( \mathcal{B} \) is fair.
→ Secondly, fix \( \alpha = 30\% \) and report the respective values.
→ \( \alpha \) ”stabilizes” the option value.

</tbody>
</table>

**Table:** Option valuation in contract $S$.

Reported results are for a fair underlying contract $B$, $x = 30$, $r = 4\%$, $g = 3\%$ and $\sigma = 0.20$.

$\rightarrow \quad \Pi^K_0(O^{S})$ is zero within the considered modeling frame.

$\rightarrow$ However risk situation when offering the contract $S$ is not alike offering a contract $B$ since the non-zero upper bound $\Pi^\text{max}_0(O^{S})$. 
4. Numerical results and discussion – Contract $S$ with surrender option

Sensitivity analysis of $\Pi_0(O^{S(\theta)})$ for different $\gamma^S_{\theta}$

![Graph showing the net present value of contract payoff $\Pi_0(O^{S(\theta)})$ for different $\gamma^S_{\theta}$.]

**Figure:** $\Pi_0(O^{S(\theta)})$ for different $\gamma^S_{\theta} = \gamma^S = -1.0\%, \ldots, 1.0\%$.

→ **In practice, many contracts set** $\gamma^S_{\theta} = -1$ **for the first two years, and zero for the following years.**
→ **Comparison with examples in Bacinello (2003b): models can be calibrated through setting the parameter** $\gamma^S_{\theta}$. [Reserve-linked modeling corresponds in this case to an additional (almost negligible) loading < 0.1% on the assets.]
4. Numerical results and discussion – Contract $Q$ with paid-up and surrender options

Option payoff $\Pi_0(O^Q(\tau, \theta))$ as a function of $\tau$ and $\theta$

(a) $\Pi_0(O^Q(\tau, \theta))$ with $\gamma^Q_{\theta} = 0.0\%$.

(b) $\Pi_0(O^Q(\tau, \theta))$ with $\gamma^Q_{\theta} = 0.5\%$.

Figure: $\Pi_0(O^Q(\tau, \theta))$ and sensitivity with $\gamma^Q_{\theta}$ as a function of $\tau$ and $\theta$.

$\rightarrow \Pi_0(O^Q(\tau, \theta))$ maximal for $\tau = 5$, $\theta = 10$; maximum not higher than in the contract $P$.

$\rightarrow \gamma^R_{\nu} = \gamma^R$ to 0.5\%: payoff is maximal for $\tau = 6$, $\theta = 9$. 

J. Wagner, A Joint Option Valuation in Participating Life Insurance Contracts, WRIEC, Singapore, July 2010
4. Numerical results and discussion – Contract \( \mathcal{Q} \) with paid-up and surrender options

## Option valuation in contract \( \mathcal{Q} \)

<table>
<thead>
<tr>

<tr>
<td></td>
<td>Value / PVP</td>
<td>0.6%</td>
<td>0.6%</td>
<td>5.7%</td>
</tr>
</tbody>
</table>

**Table:** Option valuation in contract \( \mathcal{Q} \).

Reported results are for a fair underlying contract \( \mathcal{B} \), \( x = 30 \), \( r = 4\% \), \( g = 3\% \) and \( \sigma = 0.20 \).

\[ \Pi_0^{K,L}(\mathcal{O}_\mathcal{Q}) = \Pi_0^K(\mathcal{O}_\mathcal{P}), \text{ hence the surrender option value is again zero.} \]

\[ \mathcal{R} \text{ and } \mathcal{Q} \text{ are very similar since the additional option offered is zero-valued (with } \gamma^\mathcal{R}_\tau = \gamma^\mathcal{Q}_\theta = 0). \]

\[ \text{Joint valuation is in general not equal to the sum of the single options:} \]

- **Contract \( \mathcal{P} \) with } \gamma^\mathcal{P} = 0.0\%: \Pi_0^K(\mathcal{O}_\mathcal{P}) = 33.5 \]
- **Contract \( \mathcal{S} \) with } \gamma^\mathcal{S} = 0.5\%: \Pi_0^K(\mathcal{O}_\mathcal{S}) = 45.5 \]
- **Contract \( \mathcal{Q} \) with } \gamma^\mathcal{Q} = 0.5\%: \Pi_0^{K,L}(\mathcal{O}_\mathcal{Q}) = 56.0 \]
Conclusion

• Model framework dealing with fair and joint valuation of embedded options; implementation of a robust numerical algorithm.

• Drivers of the option values pointed out:
  ▶ Conversion mechanism of the guaranteed benefits.
    → Throughout the studied situations, paid-up option values are of the order of 1 – 3% of the expected premium payments.
  ▶ Exercise behavior of the policyholder.
    → Even though an optimal exercise behavior may not be the empirically relevant case, nor the upper bound for the inherited risk be reached in practice, the practical relevance of adequate pricing is shown to be important.

• Substantial value of embedded options shows the necessity of appropriate pricing and adequate risk management.
  → Values of embedded options should be detailed carefully in particular with regard to the offered benefits and under various hypotheses of the client’s exercise behavior.

Algorithm 1 Definition of the optimal exercise strategy $K = (0; k_1] \times \ldots \times (0; k_{T-1}]$.

Initialize $k_0 = 0, \vartheta = 1, \ldots, T - 1$. Let $K_T = \mathbb{R}$.
Approximate $k_0, \vartheta = T - 1, \ldots, 1$, as follows:
Generate $N$ Monte Carlo paths, denoted with superscript $i$, of $S^i_t$, $t = 1, \ldots, T$.

for times $\vartheta = T - 1$ down to 1 do \{backward induction\}
for $k_0 = 0$ to $A^K$ in steps of $a^K$ do
for paths $i = 1$ to $N$ do
Initialize $\tau^i = 0$.
for $t = \vartheta$ to $T$ do
if $\tau^i = 0$ and $A^i_t \in K^\tau_t = (0; k^\tau_t]$ then
Let $\tau^i = t$.
end if
end for \{t\}
Calculate $e^{-r\tau^i} \tau^i p_x C_{\tau^i}(\mathcal{O}[\mathcal{X}(\tau^i)]$.
end for \{i\}
Calculate $\frac{1}{N} \sum_{i=1}^{N} e^{-r\tau^i} \tau^i p_x C_{\tau^i}(\mathcal{O}[\mathcal{X}(\tau^i)])$ as an estimate of $\Pi^K_0(\mathcal{O}[\mathcal{X}]$.
end for \{k_0\}
Choose $k_0$ from all tested values such that the estimate of $\Pi^K_0(\mathcal{O}[\mathcal{X}]$ is maximal.
end for \{\vartheta\}
Algorithm 2 Calculation of the Monte Carlo approximation of $\Pi_0^K(\mathcal{O}^X)$. 

Use $K = K_1 \times \ldots \times K_{T-1}$ determined through Algorithm 1. Let $K_T = \mathbb{R}$. Generate $N$ Monte Carlo paths, denoted with superscript $i$, of $S_t^i$, $t = 1, \ldots, T$.

for paths $i = 1$ to $N$ do 
    Initialize $\tau^i = 0$.
    for $t = 1$ to $T$ do 
        if $\tau^i = 0$ and $A_t^i \in K_t$ then 
            {exercise of option on path $i$ under strategy $K$} 
            Let $\tau^i = t$.
        end if 
    end for 
    Calculate $e^{-r\tau^i} \tau^i p_x C_{\tau^i}(\mathcal{O}^X(\tau^i))$.
end for 

Calculate $\frac{1}{N} \sum_{i=1}^{N} e^{-r\tau^i} \tau^i p_x C_{\tau^i}(\mathcal{O}^X(\tau^i))$ as an estimate of $\Pi_0^K(\mathcal{O}^X)$.
